

# ABSTRACT

A method is disclosed for accessing at least one image file transferred from a digital camera to a host computer by producing icons  
5 representative of portions of each image file, the at least one image file having a digital image and at least one audio data segment. The at least one image file is stored in a memory in the digital camera. The memory is coupled to the host computer so that the host computer identifies the at least one image file, recognizing the presence of the digital image and the at least one audio data  
10 segment in the memory. At least two icons are produced which are provided on a display associated with the host computer and which respectively represent the digital image and the at least one audio data segment. The digital image icon or the at least one audio data segment icon is then selectively accessed to cause the transfer of the digital image or the at least one audio data segment from the  
15 memory to the host computer for access by a user.
